Abstract:

The SAML V2.0 Bindings specification defines protocol bindings for the use of SAML assertions and request-response messages in communications protocols and frameworks. This document, known as an “errata composite”, combines corrections to reported errata with the original specification text. By design, the corrections are limited to clarifications of ambiguous or conflicting specification text. This document shows deletions from the original specification as struck-through text, and additions as colored underlined text. The “[*Enn*]” designations embedded in the text refer to particular errata and their dispositions.

Status:

This errata composite document is a **working draft** based on the [original](#) OASIS Standard document that had been produced by the Security Services Technical Committee and approved by the OASIS membership on 1 March 2005. While the errata corrections appearing here are non-normative, they reflect changes specified by the Approved Errata document (currently at Working Draft revision 02), which is on an OASIS standardization track. In case of any discrepancy between this document and the Approved Errata, the latter has precedence.

This document includes corrections for errata E1, E2, E4, E19, E21, E24, E31, E57, E59, E74, and E90.

Committee members should submit comments and potential errata to the security-services@lists.oasis-open.org list. Others should submit them by following the instructions at http://www.oasis-open.org/committees/comments/form.php?wg_abbrev=security.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights web page for the Security Services TC (<http://www.oasis-open.org/committees/security/ipr.php>).

1 Introduction

This document specifies SAML protocol bindings for the use of SAML assertions and request-response messages in communications protocols and frameworks.

The SAML assertions and protocols specification [SAMLCore] defines the SAML assertions and request-response messages themselves, and the SAML profiles specification [SAMLProfile] defines specific usage patterns that reference both [SAMLCore] and bindings defined in this specification or elsewhere. The SAML conformance document [SAMLConform] lists all of the specifications that comprise SAML V2.0.

1.1 Protocol Binding Concepts

Mappings of SAML request-response message exchanges onto standard messaging or communication protocols are called SAML *protocol bindings* (or just *bindings*). An instance of mapping SAML request-response message exchanges into a specific communication protocol <FOO> is termed a <FOO> *binding for SAML* or a SAML <FOO> *binding*.

For example, a SAML SOAP binding describes how SAML request and response message exchanges are mapped into SOAP message exchanges.

The intent of this specification is to specify a selected set of bindings in sufficient detail to ensure that independently implemented SAML-conforming software can interoperate when using standard messaging or communication protocols.

Unless otherwise specified, a binding should be understood to support the transmission of any SAML protocol message derived from the **samlp:RequestAbstractType** and **samlp:StatusResponseType** types. Further, when a binding refers to "SAML requests and responses", it should be understood to mean any protocol messages derived from those types.

For other terms and concepts that are specific to SAML, refer to the SAML glossary [SAMLGloss].

1.2 Notation

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this specification are to be interpreted as described in IETF RFC 2119 [RFC2119].

Listings of productions or other normative code appear like this.

Example code listings appear like this.

Note: Notes like this are sometimes used to highlight non-normative commentary.

Conventional XML namespace prefixes are used throughout this specification to stand for their respective namespaces as follows, whether or not a namespace declaration is present in the example:

Prefix	XML Namespace	Comments
saml:	urn:oasis:names:tc:SAML:2.0:assertion	This is the SAML V2.0 assertion namespace [SAMLCore].
samlp:	urn:oasis:names:tc:SAML:2.0:protocol	This is the SAML V2.0 protocol namespace [SAMLCore].
ds:	http://www.w3.org/2000/09/xmldsig#	This namespace is defined in the XML Signature Syntax and Processing specification [XMLSig] and

Prefix	XML Namespace	Comments
		its governing schema.
SOAP-ENV:	http://schemas.xmlsoap.org/soap/envelope	This namespace is defined in SOAP V1.1 [SOAP11].

223 This specification uses the following typographical conventions in text: `<ns:Element>`, `XMLAttribute`,
224 **Datatype**, `OtherKeyword`. In some cases, angle brackets are used to indicate non-terminals, rather than
225 XML elements; the intent will be clear from the context.

2 Guidelines for Specifying Additional Protocol Bindings

This specification defines a selected set of protocol bindings, but others will possibly be developed in the future. It is not possible for the OASIS Security Services Technical Committee (SSTC) to standardize all of these additional bindings for two reasons: it has limited resources and it does not own the standardization process for all of the technologies used. This section offers guidelines for third parties who wish to specify additional bindings.

The SSTC welcomes submission of proposals from OASIS members for new protocol bindings. OASIS members may wish to submit these proposals for consideration by the SSTC in a future version of this specification. Other members may simply wish to inform the committee of their work related to SAML. Please refer to the SSTC web site [SSTCWeb] for further details on how to submit such proposals to the SSTC.

Following is a checklist of issues that MUST be addressed by each protocol binding:

1. Specify three pieces of identifying information: a URI that uniquely identifies the protocol binding, postal or electronic contact information for the author, and a reference to previously defined bindings or profiles that the new binding updates or obsoletes.
2. Describe the set of interactions between parties involved in the binding. Any restrictions on applications used by each party and the protocols involved in each interaction must be explicitly called out.
3. Identify the parties involved in each interaction, including how many parties are involved and whether intermediaries may be involved.
4. Specify the method of authentication of parties involved in each interaction, including whether authentication is required and acceptable authentication types.
5. Identify the level of support for message integrity, including the mechanisms used to ensure message integrity.
6. Identify the level of support for confidentiality, including whether a third party may view the contents of SAML messages and assertions, whether the binding requires confidentiality, and the mechanisms recommended for achieving confidentiality.
7. Identify the error states, including the error states at each participant, especially those that receive and process SAML assertions or messages.
8. Identify security considerations, including analysis of threats and description of countermeasures.
9. Identify metadata considerations, such that support for a binding involving a particular communications protocol or used in a particular profile can be advertised in an efficient and interoperable way.

3 Protocol Bindings

The following sections define the protocol bindings that are specified as part of the SAML standard.

3.1 General Considerations

The following sections describe normative characteristics of all protocol bindings defined for SAML.

3.1.1 Use of RelayState

Some bindings define a "RelayState" mechanism for preserving and conveying state information. When such a mechanism is used in conveying a request message as the initial step of a SAML protocol, it places requirements on the selection and use of the binding subsequently used to convey the response. Namely, if a SAML request message is accompanied by RelayState data, then the SAML responder MUST return its SAML protocol response using a binding that also supports a RelayState mechanism, and it MUST place the exact RelayState data it received with the request into the corresponding RelayState parameter in the response.

[E90] Some bindings that define a "RelayState" mechanism do not provide for end to end origin authentication or integrity protection of the RelayState value. Most such bindings are defined in conjunction with HTTP, and RelayState is often involved in the preservation of HTTP resource state that may involve the use of HTTP redirects, or embedding of RelayState information in HTTP responses, HTML content, etc. In such cases, implementations need to beware of Cross-Site Scripting (XSS) and other attack vectors (e.g., Cross-Site Request Forgery, CSRF) that are common to such scenarios.

Implementations MUST carefully sanitize the URL schemes they permit (for example, disallowing anything but "http" or "https"), and should disallow unencoded characters that may be used in mounting such attacks. This caution applies to both identity and service provider implementations.

3.1.2 Security

Unless stated otherwise, these security statements apply to all bindings. Bindings may also make additional statements about these security features.

3.1.2.1 Use of SSL 3.0 or TLS 1.0

Unless otherwise specified, in any SAML binding's use of SSL 3.0 [SSL3] or TLS 1.0 [RFC2246], servers MUST authenticate to clients using a X.509 v3 certificate. The client MUST establish server identity based on contents of the certificate (typically through examination of the certificate's subject DN field, subjectAltName attribute, etc.).

3.1.2.2 Data Origin Authentication

Authentication of both the SAML requester and the SAML responder associated with a message is OPTIONAL and depends on the environment of use. Authentication mechanisms available at the SOAP message exchange layer or from the underlying substrate protocol (for example in many bindings the SSL/TLS or HTTP protocol) MAY be utilized to provide data origin authentication.

Transport authentication will not meet end-end origin-authentication requirements in bindings where the SAML protocol message passes through an intermediary – in this case message authentication is recommended.

Note that SAML itself offers mechanisms for parties to authenticate to one another, but in addition SAML

298 may use other authentication mechanisms to provide security for SAML itself.

299 **3.1.2.3 Message Integrity**

300 Message integrity of both SAML requests and SAML responses is OPTIONAL and depends on the
301 environment of use. The security layer in the underlying substrate protocol or a mechanism at the SOAP
302 message exchange layer MAY be used to ensure message integrity.

303 Transport integrity will not meet end-end integrity requirements in bindings where the SAML protocol
304 message passes through an intermediary – in this case message integrity is recommended.

305 **3.1.2.4 Message Confidentiality**

306 Message confidentiality of both SAML requests and SAML responses is OPTIONAL and depends on the
307 environment of use. The security layer in the underlying substrate protocol or a mechanism at the SOAP
308 message exchange layer MAY be used to ensure message confidentiality.

309 Transport confidentiality will not meet end-end confidentiality requirements in bindings where the SAML
310 protocol message passes through an intermediary.

311 **3.1.2.5 Security Considerations**

312 Before deployment, each combination of authentication, message integrity, and confidentiality
313 mechanisms SHOULD be analyzed for vulnerability in the context of the specific protocol exchange and
314 the deployment environment. See specific protocol processing rules in [SAMLCore] and the SAML
315 security considerations document [SAMLSecure] for a detailed discussion.

316 IETF RFC 2617 [RFC2617] describes possible attacks in the HTTP environment when basic or message-
317 digest authentication schemes are used.

318 Special care should be given to the impact of possible caching on security.

319 **3.2 SAML SOAP Binding**

320 SOAP is a lightweight protocol intended for exchanging structured information in a decentralized,
321 distributed environment [SOAP11]. It uses XML technologies to define an extensible messaging
322 framework providing a message construct that can be exchanged over a variety of underlying protocols.
323 The framework has been designed to be independent of any particular programming model and other
324 implementation specific semantics. Two major design goals for SOAP are simplicity and extensibility.
325 SOAP attempts to meet these goals by omitting, from the messaging framework, features that are often
326 found in distributed systems. Such features include but are not limited to "reliability", "security",
327 "correlation", "routing", and "Message Exchange Patterns" (MEPs).

328 A SOAP message is fundamentally a one-way transmission between SOAP nodes from a SOAP sender
329 to a SOAP receiver, possibly routed through one or more SOAP intermediaries. SOAP messages are
330 expected to be combined by applications to implement more complex interaction patterns ranging from
331 request/response to multiple, back-and-forth "conversational" exchanges [SOAP-PRIMER].

332 SOAP defines an XML message envelope that includes header and body sections, allowing data and
333 control information to be transmitted. SOAP also defines processing rules associated with this envelope
334 and an HTTP binding for SOAP message transmission.

335 The SAML SOAP binding defines how to use SOAP to send and receive SAML requests and responses.

336 Like SAML, SOAP can be used over multiple underlying transports. This binding has protocol-
337 independent aspects, but also calls out the use of SOAP over HTTP as REQUIRED (mandatory to
338 implement).

3.2.1 Required Information

Identification: urn:oasis:names:tc:SAML:2.0:bindings:SOAP

Contact information: security-services-comment@lists.oasis-open.org

Description: Given below.

Updates: urn:oasis:names:tc:SAML:1.0:bindings:SOAP-binding

3.2.2 Protocol-Independent Aspects of the SAML SOAP Binding

The following sections define aspects of the SAML SOAP binding that are independent of the underlying protocol, such as HTTP, on which the SOAP messages are transported. Note this binding only supports the use of SOAP 1.1.

3.2.2.1 Basic Operation

SOAP 1.1 messages consist of three elements: an envelope, header data, and a message body. SAML request-response protocol elements MUST be enclosed within the SOAP message body.

SOAP 1.1 also defines an optional data encoding system. This system is not used within the SAML SOAP binding. This means that SAML messages can be transported using SOAP without re-encoding from the "standard" SAML schema to one based on the SOAP encoding.

The system model used for SAML conversations over SOAP is a simple request-response model.

1. A system entity acting as a SAML requester transmits a SAML request element within the body of a SOAP message to a system entity acting as a SAML responder. The SAML requester MUST NOT include more than one SAML request per SOAP message or include any additional XML elements in the SOAP body.
2. The SAML responder [E19]SHOULD return a SOAP message containing either a SAML response element in the body or a SOAP fault. The SAML responder MUST NOT include more than one SAML response per SOAP message or include any additional XML elements in the SOAP body. SOAP fault codes SHOULD NOT be sent for errors within the SAML problem domain, for example, inability to find an extension schema or as a signal that the subject is not authorized to access a resource in an authorization query. See Section 3.2.3.3 for more information about error handling. (SOAP 1.1 faults and fault codes are discussed in [SOAP11] Section 4.1.)

On receiving a SAML response in a SOAP message, the SAML requester MUST NOT send a fault code or other error messages to the SAML responder. Since the format for the message interchange is a simple request-response pattern, adding additional items such as error conditions would needlessly complicate the protocol.

[SOAP11] references an early draft of the XML Schema specification including an obsolete namespace. SAML requesters SHOULD generate SOAP documents referencing only the final XML schema namespace. SAML responders MUST be able to process both the XML schema namespace used in [SOAP11] as well as the final XML schema namespace.

3.2.2.2 SOAP Headers

A SAML requester in a SAML conversation over SOAP MAY add arbitrary headers to the SOAP message. This binding does not define any additional SOAP headers.

Note: The reason other headers need to be allowed is that some SOAP software and libraries might add headers to a SOAP message that are out of the control of the SAML-aware process. Also, some headers might be needed for underlying protocols that require routing of messages or by message security mechanisms.

A SAML responder MUST NOT require any headers in the SOAP message in order to process the SAML message correctly itself, but MAY require additional headers that address underlying routing or message security requirements.

Note: The rationale is that requiring extra headers will cause fragmentation of the SAML standard and will hurt interoperability.

3.2.3 Use of SOAP over HTTP

A SAML processor that claims conformance to the SAML SOAP binding MUST implement SAML over SOAP over HTTP. This section describes certain specifics of using SOAP over HTTP, including HTTP headers, caching, and error reporting.

The HTTP binding for SOAP is described in [SOAP11] Section 6.0. It requires the use of a `SOAPAction` header as part of a SOAP HTTP request. A SAML responder MUST NOT depend on the value of this header. A SAML requester MAY set the value of the `SOAPAction` header as follows:

`http://www.oasis-open.org/committees/security`

3.2.3.1 HTTP Headers

A SAML requester in a SAML conversation over SOAP over HTTP MAY add arbitrary headers to the HTTP request. This binding does not define any additional HTTP headers.

Note: The reason other headers need to be allowed is that some HTTP software and libraries might add headers to an HTTP message that are out of the control of the SAML-aware process. Also, some headers might be needed for underlying protocols that require routing of messages or by message security mechanisms.

A SAML responder MUST NOT require any headers in the HTTP request to correctly process the SAML message itself, but MAY require additional headers that address underlying routing or message security requirements.

Note: The rationale is that requiring extra headers will cause fragmentation of the SAML standard and will hurt interoperability.

3.2.3.2 Caching

HTTP proxies should not cache SAML protocol messages. To ensure this, the following rules SHOULD be followed.

When using HTTP 1.1 [RFC2616], requesters SHOULD:

- Include a `Cache-Control` header field set to "no-cache, no-store".
- Include a `Pragma` header field set to "no-cache".

When using HTTP 1.1, responders SHOULD:

- Include a `Cache-Control` header field set to "no-cache, no-store, must-revalidate, private".
- Include a `Pragma` header field set to "no-cache".
- NOT include a `Validator`, such as a `Last-Modified` or `ETag` header.

3.2.3.3 Error Reporting

A SAML responder that refuses to perform a message exchange with the SAML requester SHOULD return a "403 Forbidden" response. In this case, the content of the HTTP body is not significant.

As described in [SOAP11] Section 6.2, in the case of a SOAP error while processing a SOAP request, the SOAP HTTP server MUST return a "500 Internal Server Error" response and include a SOAP message in the response with a SOAP <SOAP-ENV:fault> element. This type of error SHOULD be returned for SOAP-related errors detected before control is passed to the SAML processor, or when the SOAP processor reports an internal error (for example, the SOAP XML namespace is incorrect, the SAML schema cannot be located, the SAML processor throws an exception, and so on).

In the case of a SAML processing error, the SOAP HTTP server [E19]SHOULD respond with "200 OK" and include a SAML-specified <samlp:Status> element in the SAML response within the SOAP body. Note that the <samlp:Status> element does not appear by itself in the SOAP body, but only within a SAML response of some sort.

For more information about the use of SAML status codes, see the SAML assertions and protocols specification [SAMLCore].

3.2.3.4 Metadata Considerations

Support for the SOAP binding SHOULD be reflected by indicating either a URL endpoint at which requests contained in SOAP messages for a particular protocol or profile are to be sent, or alternatively with a WSDL port/endpoint definition.

3.2.3.5 Example SAML Message Exchange Using SOAP over HTTP

Following is an example of a query that asks for an assertion containing an attribute statement from a SAML attribute authority.

```
POST /SamlService HTTP/1.1
Host: www.example.com
Content-Type: text/xml
Content-Length: nnn
SOAPAction: http://www.oasis-open.org/committees/security
<SOAP-ENV:Envelope
  xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
  <SOAP-ENV:Body>
    <samlp:AttributeQuery xmlns:samlp="..."
      xmlns:saml="..." xmlns:ds="..." ID="_6c3a4f8b9c2d" Version="2.0"
      IssueInstant="2004-03-27T08:41:00Z"
        <ds:Signature> ... </ds:Signature>
        <saml:Subject>
          ...
        </saml:Subject>
      </samlp:AttributeQuery>
    </SOAP-ENV:Body>
  </SOAP-ENV:Envelope>
```

Following is an example of the corresponding response, which supplies an assertion containing the attribute statement as requested.

```
HTTP/1.1 200 OK
Content-Type: text/xml
Content-Length: nnnn
<SOAP-ENV:Envelope
  xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
  <SOAP-ENV:Body>
    <samlp:Response xmlns:samlp="..." xmlns:saml="..." xmlns:ds="..."
      ID="_6c3a4f8b9c2d" Version="2.0" IssueInstant="2004-03-27T08:42:00Z">
      <saml:Issuer>https://www.example.com/SAML</saml:Issuer>
```

```

468         <ds:Signature> ... </ds:Signature>
469         <Status>
470             <StatusCode Value="..." />
471         </Status>
472
473         <saml:Assertion>
474             <saml:Subject>
475                 ...
476             </saml:Subject>
477             <saml:AttributeStatement>
478                 ...
479             </saml:AttributeStatement>
480         </saml:Assertion>
481     </samlp:Response>
482 </SOAP-Env:Body>
483 </SOAP-ENV:Envelope>

```

484 3.3 Reverse SOAP (PAOS) Binding

485 This binding leverages the Reverse HTTP Binding for SOAP specification [PAOS]. Implementers MUST
 486 comply with the general processing rules specified in [PAOS] in addition to those specified in this
 487 document. In case of conflict, [PAOS] is normative.

488 3.3.1 Required Information

489 **Identification:** urn:oasis:names:tc:SAML:2.0:bindings:PAOS

490 **Contact information:** security-services-comment@lists.oasis-open.org

491 **Description:** Given below.

492 **Updates:** None.

493 3.3.2 Overview

494 The reverse SOAP binding is a mechanism by which an HTTP requester can advertise the ability to act
 495 as a SOAP responder or a SOAP intermediary to a SAML requester. The HTTP requester is able to
 496 support a pattern where a SAML request is sent to it in a SOAP envelope in an HTTP response from the
 497 SAML requester, and the HTTP requester responds with a SAML response in a SOAP envelope in a
 498 subsequent HTTP request. This message exchange pattern supports the use case defined in the ECP
 499 SSO profile (described in the SAML profiles specification [SAMLProfile]), in which the HTTP requester is
 500 an intermediary in an authentication exchange.

501 3.3.3 Message Exchange

502 The PAOS binding includes two component message exchange patterns:

- 503 1. The HTTP requester sends an HTTP request to a SAML requester. The SAML requester responds
 504 with an HTTP response containing a SOAP envelope containing a SAML request message.
- 505 2. Subsequently, the HTTP requester sends an HTTP request to the original SAML requester
 506 containing a SOAP envelope containing a SAML response message. The SAML requester
 507 responds with an HTTP response, possibly in response to the original service request in step 1.

508 The ECP profile uses the PAOS binding to provide authentication of the client to the service provider
 509 before the service is provided. This occurs in the following steps, illustrated in Figure A:

- 510 1. The client requests a service using an HTTP request.
- 511 2. The service provider responds with a SAML authentication request. This is sent using a SOAP
 512 request, carried in the HTTP response.

- 513 3. The client returns a SOAP response carrying a SAML authentication response. This is sent using a
 514 new HTTP request.
- 515 4. Assuming the service provider authentication and authorization is successful, the service provider
 516 may respond to the original service request in the HTTP response.

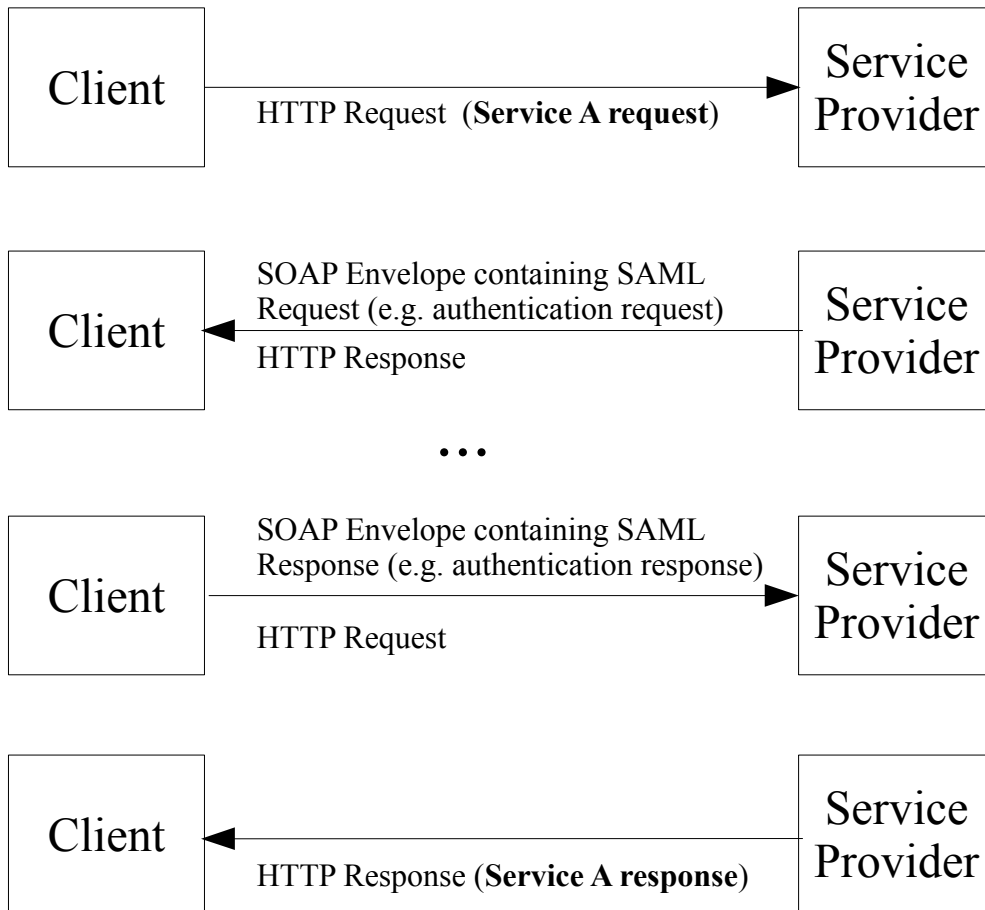

Figure 1: PAOS Binding Message Exchanges

517 The HTTP requester advertises the ability to handle this reverse SOAP binding in its HTTP requests
 518 using the HTTP headers defined by the PAOS specification. Specifically:

- 519 • The HTTP `Accept` Header field MUST indicate an ability to accept the
 520 "application/vnd.paos+xml" content type.
- 521 • The HTTP `PAOS` Header field MUST be present and specify the PAOS version with
 522 "urn:liberty:paos:2003-08"[E21].

523 Additional PAOS headers such as the service value MAY be specified by profiles that use the PAOS
 524 binding. The HTTP requester MAY add arbitrary headers to the HTTP request.

525 Note that this binding does not define a RelayState mechanism. Specific profiles that make use of this
 526 binding must therefore define such a mechanism, if needed. The use of a SOAP header is suggested for
 527 this purpose.

528 The following sections provide more detail on the two steps of the message exchange.

3.3.3.1 HTTP Request, SAML Request in SOAP Response

In response to an arbitrary HTTP request, the HTTP responder MAY return a SAML request message using this binding by returning a SOAP 1.1 envelope in the HTTP response containing a single SAML request message in the SOAP body, with no additional body content. The SOAP envelope MAY contain arbitrary SOAP headers defined by PAOS, SAML profiles, or additional specifications.

Note that while the SAML request message is delivered to the HTTP requester, the actual intended recipient MAY be another system entity, with the HTTP requester acting as an intermediary, as defined by specific profiles.

3.3.3.2 SAML Response in SOAP Request, HTTP Response

When the HTTP requester delivers a SAML response message to the intended recipient using the PAOS binding, it places it as the only element in the SOAP body in a SOAP envelope in an HTTP request. The HTTP requester may or may not be the originator of the SAML response. The SOAP envelope MAY contain arbitrary SOAP headers defined by PAOS, SAML profiles, or additional specifications. The SAML exchange is considered complete and the HTTP response is unspecified by this binding.

Profiles MAY define additional constraints on the HTTP content of non-SOAP responses during the exchanges covered by this binding.

3.3.4 Caching

HTTP proxies should not cache SAML protocol messages. To ensure this, the following rules SHOULD be followed.

When using HTTP 1.1, requesters sending SAML protocol messages SHOULD:

- Include a `Cache-Control` header field set to "no-cache, no-store".
- Include a `Pragma` header field set to "no-cache".

When using HTTP 1.1, responders returning SAML protocol messages SHOULD:

- Include a `Cache-Control` header field set to "no-cache, no-store, must-revalidate, private".
- Include a `Pragma` header field set to "no-cache".
- NOT include a `Validator`, such as a `Last-Modified` or `ETag` header.

3.3.5 Security Considerations

The HTTP requester in the PAOS binding may act as a SOAP intermediary and when it does, transport layer security for origin authentication, integrity and confidentiality may not meet end-end security requirements. In this case security at the SOAP message layer is [E31]RECOMMENDED.

3.3.5.1 Error Reporting

Standard HTTP and SOAP error conventions MUST be observed. Errors that occur during SAML processing MUST NOT be signaled at the HTTP or SOAP layer and MUST be handled using SAML response messages with an error `<samlp:Status>` element.

3.3.5.2 Metadata Considerations

Support for the PAOS binding SHOULD be reflected by indicating a URL endpoint at which HTTP requests and/or SAML protocol messages contained in SOAP envelopes for a particular protocol or

profile are to be sent. Either a single endpoint or distinct request and response endpoints MAY be supplied.

3.4 HTTP Redirect Binding

The HTTP Redirect binding defines a mechanism by which SAML protocol messages can be transmitted within URL parameters. Permissible URL length is theoretically infinite, but unpredictably limited in practice. Therefore, specialized encodings are needed to carry XML messages on a URL, and larger or more complex message content can be sent using the HTTP POST or Artifact bindings.

This binding MAY be composed with the HTTP POST binding (see Section 3.5) and the HTTP Artifact binding (see Section 3.6) to transmit request and response messages in a single protocol exchange using two different bindings.

This binding involves the use of a message encoding. While the definition of this binding includes the definition of one particular message encoding, others MAY be defined and used.

3.4.1 Required Information

Identification: urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect

Contact information: security-services-comment@lists.oasis-open.org

Description: Given below.

Updates: None.

3.4.2 Overview

The HTTP Redirect binding is intended for cases in which the SAML requester and responder need to communicate using an HTTP user agent (as defined in HTTP 1.1 [RFC2616]) as an intermediary. This may be necessary, for example, if the communicating parties do not share a direct path of communication. It may also be needed if the responder requires an interaction with the user agent in order to fulfill the request, such as when the user agent must authenticate to it.

Note that some HTTP user agents may have the capacity to play a more active role in the protocol exchange and may support other bindings that use HTTP, such as the SOAP and Reverse SOAP bindings. This binding assumes nothing apart from the capabilities of a common web browser.

3.4.3 RelayState

RelayState data MAY be included with a SAML protocol message transmitted with this binding. The value MUST NOT exceed 80 bytes in length and SHOULD be integrity protected by the entity creating the message[E1], either via a digital signature (see Section 3.4.4.1) or by some independent means.

If a SAML request message is accompanied by RelayState data, then the SAML responder MUST return its SAML protocol response using a binding that also supports a RelayState mechanism, and it MUST place the exact data it received with the request into the corresponding RelayState parameter in the response.

If no such value is included with a SAML request message, or if the SAML response message is being generated without a corresponding request, then the SAML responder MAY include RelayState data to be interpreted by the recipient based on the use of a profile or prior agreement between the parties.

3.4.4 Message Encoding

Messages are encoded for use with this binding using a URL encoding technique, and transmitted using

the HTTP GET method. There are many possible ways to encode XML into a URL, depending on the constraints in effect. This specification defines one such method without precluding others. Binding endpoints SHOULD indicate which encodings they support using metadata, when appropriate. Particular encodings MUST be uniquely identified with a URI when defined. It is not a requirement that all possible SAML messages be encodable with a particular set of rules, but the rules MUST clearly indicate which messages or content can or cannot be so encoded.

A URL encoding MUST place the message entirely within the URL query string, and MUST reserve the rest of the URL for the endpoint of the message recipient.

A query string parameter named `SAMLEncoding` is reserved to identify the encoding mechanism used. If this parameter is omitted, then the value is assumed to be `urn:oasis:names:tc:SAML:2.0:bindings:URL-Encoding:DEFLATE`.

All endpoints that support this binding MUST support the DEFLATE encoding described in the following sub-section.

3.4.4.1 DEFLATE Encoding

Identification: `urn:oasis:names:tc:SAML:2.0:bindings:URL-Encoding:DEFLATE`

SAML protocol messages can be encoded into a URL via the DEFLATE compression method (see [RFC1951]). In such an encoding, the following procedure should be applied to the original SAML protocol message's XML serialization:

1. Any signature on the SAML protocol message, including the `<ds:Signature>` XML element itself, MUST be removed. Note that if the content of the message includes another signature, such as a signed SAML assertion, this embedded signature is not removed. However, the length of such a message after encoding essentially precludes using this mechanism. Thus SAML protocol messages that contain signed content SHOULD NOT be encoded using this mechanism.
2. The DEFLATE compression mechanism, as specified in [RFC1951] is then applied to the entire remaining XML content of the original SAML protocol message.
3. The compressed data is subsequently base64-encoded according to the rules specified in IETF RFC 2045 [RFC2045]. Linefeeds or other whitespace MUST be removed from the result.
4. The base-64 encoded data is then URL-encoded, and added to the URL as a query string parameter which MUST be named `SAMLRequest` (if the message is a SAML request) or `SAMLResponse` (if the message is a SAML response).
5. If RelayState data is to accompany the SAML protocol message, it MUST be URL-encoded and placed in an additional query string parameter named `RelayState`.
6. If the original SAML protocol message was signed using an XML digital signature, a new signature covering the encoded data as specified above MUST be attached using the rules stated below.

XML digital signatures are not directly URL-encoded according to the above rules, due to space concerns. If the underlying SAML protocol message is signed with an XML signature [XMLSig], the URL-encoded form of the message MUST be signed as follows:

1. The signature algorithm identifier MUST be included as an additional query string parameter, named `SigAlg`. The value of this parameter MUST be a URI that identifies the algorithm used to sign the URL-encoded SAML protocol message, specified according to [XMLSig] or whatever specification governs the algorithm.
2. To construct the signature, a string consisting of the concatenation of the `RelayState` (if present), `SigAlg`, and `SAMLRequest` (or `SAMLResponse`) query string parameters (each one URL-encoded) is constructed in one of the following ways (ordered as below):

```
SAMLRequest=value&RelayState=value&SigAlg=value  
SAMLResponse=value&RelayState=value&SigAlg=value
```

3. The resulting string of bytes is the octet string to be fed into the signature algorithm. Any other

content in the original query string is not included and not signed.

4. The signature value MUST be encoded using the base64 encoding (see RFC 2045 [RFC2045]) with any whitespace removed, and included as a query string parameter named *Signature*. Note that some characters in the base64-encoded signature value may themselves require URL-encoding before being added.
5. The following signature algorithms (see [XMLSig]) and their URI representations MUST be supported with this encoding mechanism:
 - DSAwithSHA1 – <http://www.w3.org/2000/09/xmldsig#dsa-sha1>
 - RSAwithSHA1 – <http://www.w3.org/2000/09/xmldsig#rsa-sha1>

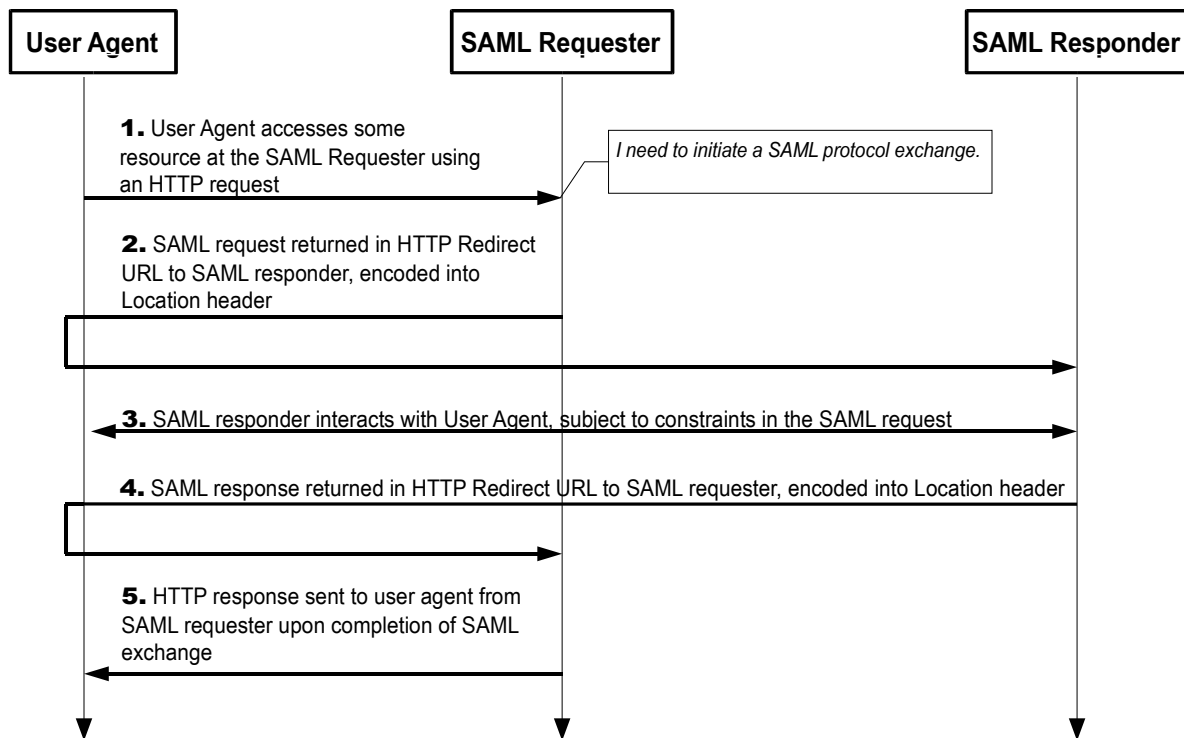

Note that when verifying signatures, the order of the query string parameters on the resulting URL to be verified is not prescribed by this binding. The parameters may appear in any order. Before verifying a signature, if any, the relying party MUST ensure that the parameter values to be verified are ordered as required by the signing rules above.

Further, note that URL-encoding is not canonical; that is, there are multiple legal encodings for a given value. The relying party MUST therefore perform the verification step using the original URL-encoded values it received on the query string. It is not sufficient to re-encode the parameters after they have been processed by software because the resulting encoding may not match the signer's encoding.

Finally, note that if there is no *RelayState* value, the entire parameter should be omitted from the signature computation (and not included as an empty parameter name).

3.4.5 Message Exchange

The system model used for SAML conversations via this binding is a request-response model, but these messages are sent to the user agent in an HTTP response and delivered to the message recipient in an HTTP request. The HTTP interactions before, between, and after these exchanges take place is unspecified. Both the SAML requester and the SAML responder are assumed to be HTTP responders. See the following sequence diagram illustrating the messages exchanged.

- 678 1. Initially, the user agent makes an arbitrary HTTP request to a system entity. In the course of
679 processing the request, the system entity decides to initiate a SAML protocol exchange.
- 680 2. The system entity acting as a SAML requester responds to the HTTP request from the user agent
681 in step 1 by returning a SAML request. The SAML request is returned encoded into the HTTP
682 response's Location header, and the HTTP status MUST be either 303 or 302. The SAML requester
683 MAY include additional presentation and content in the HTTP response to facilitate the user agent's
684 transmission of the message, as defined in HTTP 1.1 [RFC2616]. The user agent delivers the
685 SAML request by issuing an HTTP GET request to the SAML responder.
- 686 3. In general, the SAML responder MAY respond to the SAML request by immediately returning a
687 SAML response or MAY return arbitrary content to facilitate subsequent interaction with the user
688 agent necessary to fulfill the request. Specific protocols and profiles may include mechanisms to
689 indicate the requester's level of willingness to permit this kind of interaction (for example, the
690 `IsPassive` attribute in `<samlp:AuthnRequest>`).
- 691 4. Eventually the responder SHOULD return a SAML response to the user agent to be returned to the
692 SAML requester. The SAML response is returned in the same fashion as described for the SAML
693 request in step 2.
- 694 5. Upon receiving the SAML response, the SAML requester returns an arbitrary HTTP response to the
695 user agent.

696 3.4.5.1 HTTP and Caching Considerations

697 HTTP proxies and the user agent intermediary should not cache SAML protocol messages. To ensure
698 this, the following rules SHOULD be followed.

699 When returning SAML protocol messages using HTTP 1.1, HTTP responders SHOULD:

- 700 • Include a `Cache-Control` header field set to "no-cache, no-store".
- 701 • Include a `Pragma` header field set to "no-cache".

There are no other restrictions on the use of HTTP headers.

3.4.5.2 Security Considerations

The presence of the user agent intermediary means that the requester and responder cannot rely on the transport layer for end-end authentication, integrity and confidentiality. URL-encoded messages MAY be signed to provide origin authentication and integrity if the encoding method specifies a means for signing.

If the message is signed, the `Destination` XML attribute in the root SAML element of the protocol message MUST contain the URL to which the sender has instructed the user agent to deliver the message. The recipient MUST then verify that the value matches the location at which the message has been received.

This binding SHOULD NOT be used if the content of the request or response should not be exposed to the user agent intermediary. Otherwise, confidentiality of both SAML requests and SAML responses is OPTIONAL and depends on the environment of use. If confidentiality is necessary, SSL 3.0 [SSL3] or TLS 1.0 [RFC2246] SHOULD be used to protect the message in transit between the user agent and the SAML requester and responder.

Note also that URL-encoded messages may be exposed in a variety of HTTP logs as well as the HTTP "Referer" header.

Before deployment, each combination of authentication, message integrity, and confidentiality mechanisms SHOULD be analyzed for vulnerability in the context of the specific protocol exchange, and the deployment environment. See specific protocol processing rules in [SAMLCore], and the SAML security considerations document [SAMLSecure] for a detailed discussion.

In general, this binding relies on message-level authentication and integrity protection via signing and does not support confidentiality of messages from the user agent intermediary.

[E90] When using RelayState in conjunction with HTTP redirects or response information, implementations MUST carefully sanitize the URL schemes they permit (for example, disallowing anything but "http" or "https"), and should disallow unencoded characters that may be used in mounting such attacks.

3.4.6 Error Reporting

A SAML responder that refuses to perform a message exchange with the SAML requester SHOULD return a SAML response message with a second-level `<samlp:StatusCode>` value of `urn:oasis:names:tc:SAML:2.0:status:RequestDenied`.

HTTP interactions during the message exchange MUST NOT use HTTP error status codes to indicate failures in SAML processing, since the user agent is not a full party to the SAML protocol exchange.

For more information about SAML status codes, see the SAML assertions and protocols specification [SAMLCore].

3.4.7 Metadata Considerations

Support for the HTTP Redirect binding SHOULD be reflected by indicating URL endpoints at which requests and responses for a particular protocol or profile should be sent. Either a single endpoint or distinct request and response endpoints MAY be supplied.

3.4.8 Example SAML Message Exchange Using HTTP Redirect

In this example, a `<LogoutRequest>` and `<LogoutResponse>` message pair is exchanged using the HTTP Redirect binding.

First, here are the actual SAML protocol messages being exchanged:

```
<samlp:LogoutRequest xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
xmlns="urn:oasis:names:tc:SAML:2.0:assertion"
  ID="d2b7c388cec36fa7c39c28fd298644a8" IssueInstant="2004-01-
21T19:00:49Z" Version="2.0">
  <Issuer>https://IdentityProvider.com/SAML</Issuer>
  <NameID Format="urn:oasis:names:tc:SAML:2.0:nameid-
format:persistent">005a06e0-ad82-110d-a556-004005b13a2b</NameID>
  <samlp:SessionIndex>1</samlp:SessionIndex>
</samlp:LogoutRequest>
```

```
<samlp:LogoutResponse xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
xmlns="urn:oasis:names:tc:SAML:2.0:assertion"
  ID="b0730d21b628110d8b7e004005b13a2b"
InResponseTo="d2b7c388cec36fa7c39c28fd298644a8"
  IssueInstant="2004-01-21T19:00:49Z" Version="2.0">
  <Issuer>https://ServiceProvider.com/SAML</Issuer>
  <samlp:Status>
    <samlp:StatusCode
Value="urn:oasis:names:tc:SAML:2.0:status:Success"/>
  </samlp:Status>
</samlp:LogoutResponse>
```

The initial HTTP request from the user agent in step 1 is not defined by this binding. To initiate the logout protocol exchange, the SAML requester returns the following HTTP response, containing a signed SAML request message. The `SAMLRequest` parameter value is actually derived from the request message above. The signature portion is only illustrative and not the result of an actual computation. Note that the line feeds in the HTTP `Location` header below are an artifact of the document, and there are no line feeds in the actual header value.

```
HTTP/1.1 302 Object Moved
Date: 21 Jan 2004 07:00:49 GMT
Location: https://ServiceProvider.com/SAML/SLO/Browser?
SAMLRequest=fVFdS8MwFH0f7D%2BUvGdNsQ62oSsIQyhMESc%2B
%2BJYlmRbWpObeyvz3puv2IMjyFM7HPedyK1DdsZdb%2F

803 3.5 HTTP POST Binding

804 The HTTP POST binding defines a mechanism by which SAML protocol messages may be transmitted
805 within the base64-encoded content of an HTML form control.

806 This binding MAY be composed with the HTTP Redirect binding (see Section 3.4) and the HTTP Artifact
807 binding (see Section 3.6) to transmit request and response messages in a single protocol exchange using
808 two different bindings.

809 3.5.1 Required Information

810 **Identification:** urn:oasis:names:tc:SAML:2.0:bindings:HTTP-POST

811 **Contact information:** security-services-comment@lists.oasis-open.org

812 **Description:** Given below.

813 **Updates:** Effectively replaces the binding aspects of the Browser/POST profile in SAML V1.1
814 [SAML11Bind].

815 3.5.2 Overview

816 The HTTP POST binding is intended for cases in which the SAML requester and responder need to
817 communicate using an HTTP user agent (as defined in HTTP 1.1 [RFC2616]) as an intermediary. This
818 may be necessary, for example, if the communicating parties do not share a direct path of
819 communication. It may also be needed if the responder requires an interaction with the user agent in
820 order to fulfill the request, such as when the user agent must authenticate to it.

821 Note that some HTTP user agents may have the capacity to play a more active role in the protocol
822 exchange and may support other bindings that use HTTP, such as the SOAP and Reverse SOAP
823 bindings. This binding assumes nothing apart from the capabilities of a common web browser.

824 3.5.3 RelayState

825 RelayState data MAY be included with a SAML protocol message transmitted with this binding. The value
826 MUST NOT exceed 80 bytes in length and SHOULD be integrity protected by the entity creating the
827 message independent of any other protections that may or may not exist during message transmission.
828 Signing is not realistic given the space limitation, but because the value is exposed to third-party
829 tampering, the entity SHOULD ensure that the value has not been tampered with by using a checksum, a
830 pseudo-random value, or similar means.

831 If a SAML request message is accompanied by RelayState data, then the SAML responder MUST return
832 its SAML protocol response using a binding that also supports a RelayState mechanism, and it MUST
833 place the exact data it received with the request into the corresponding RelayState parameter in the
834 response.

If no such [E31]RelayState data is included with a SAML request message, or if the SAML response message is being generated without a corresponding request, then the SAML responder MAY include RelayState data to be interpreted by the recipient based on the use of a profile or prior agreement between the parties.

3.5.4 Message Encoding

Messages are encoded for use with this binding by encoding the XML into an HTML form control and are transmitted using the HTTP POST method. A SAML protocol message is form-encoded by applying the base-64 encoding rules to the XML representation of the message and placing the result in a hidden form control within a form as defined by [HTML401] Section 17. The HTML document MUST adhere to the XHTML specification, [XHTML]. The base64-encoded value MAY be line-wrapped at a reasonable length in accordance with common practice.

If the message is a SAML request, then the form control MUST be named `SAMLRequest`. If the message is a SAML response, then the form control MUST be named `SAMLResponse`. Any additional form controls or presentation MAY be included but MUST NOT be required in order for the recipient to process the message.

If a "RelayState" value is to accompany the SAML protocol message, it MUST be placed in an additional hidden form control named `RelayState` within the same form with the SAML message.

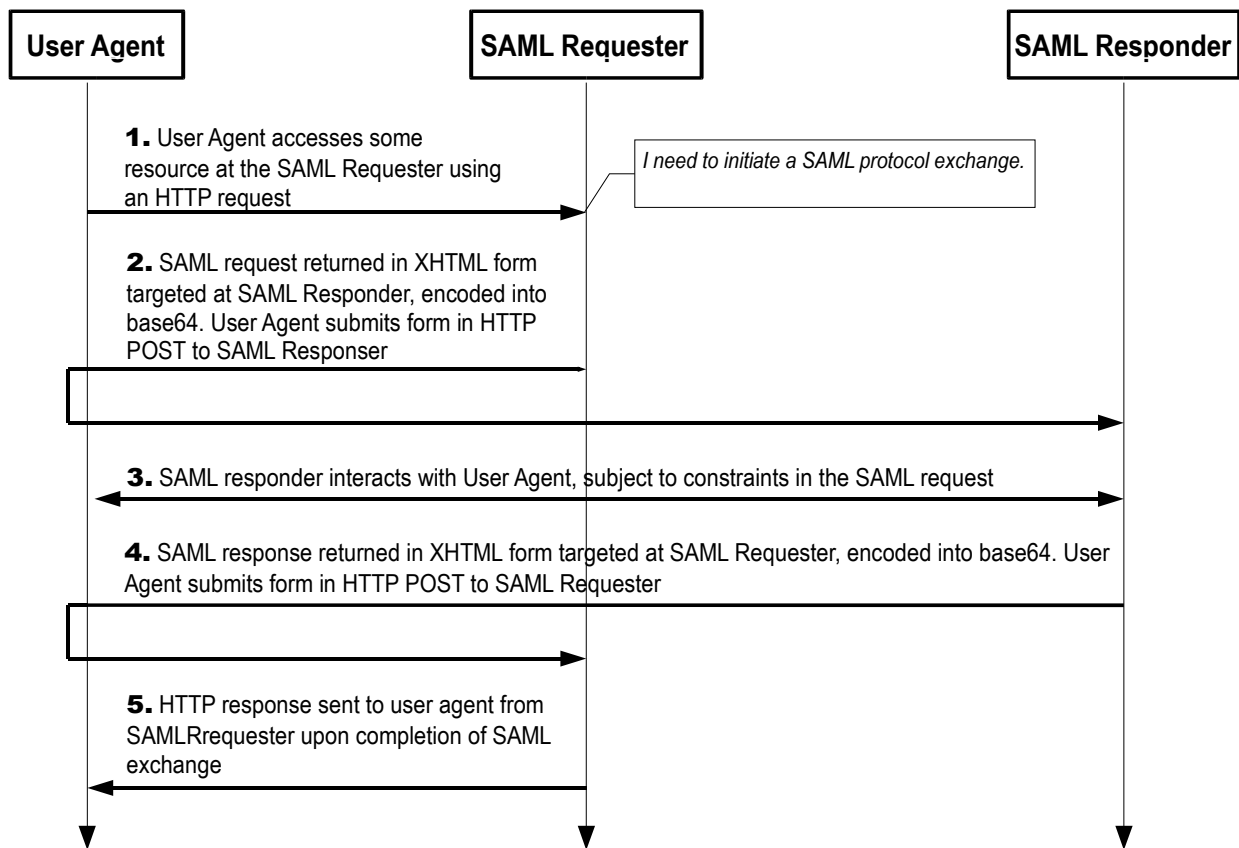

The `action` attribute of the form MUST be the recipient's HTTP endpoint for the protocol or profile using this binding to which the SAML message is to be delivered. The `method` attribute MUST be "POST".

Any technique supported by the user agent MAY be used to cause the submission of the form, and any form content necessary to support this MAY be included, such as submit controls and client-side scripting commands. However, the recipient MUST be able to process the message without regard for the mechanism by which the form submission is initiated.

Note that any form control values included MUST be transformed so as to be safe to include in the XHTML document. This includes transforming characters such as quotes into HTML entities, etc.

3.5.5 Message Exchange

The system model used for SAML conversations via this binding is a request-response model, but these messages are sent to the user agent in an HTTP response and delivered to the message recipient in an HTTP request. The HTTP interactions before, between, and after these exchanges take place is unspecified. Both the SAML requester and responder are assumed to be HTTP responders. See the following diagram illustrating the messages exchanged.

- 866 1. Initially, the user agent makes an arbitrary HTTP request to a system entity. In the course of
867 processing the request, the system entity decides to initiate a SAML protocol exchange.
- 868 2. The system entity acting as a SAML requester responds to an HTTP request from the user agent
869 by returning a SAML request. The request is returned in an XHTML document containing the form
870 and content defined in Section 3.5.4. The user agent delivers the SAML request by issuing an
871 HTTP POST request to the SAML responder.
- 872 3. In general, the SAML responder MAY respond to the SAML request by immediately returning a
873 SAML response or it MAY return arbitrary content to facilitate subsequent interaction with the user
874 agent necessary to fulfill the request. Specific protocols and profiles may include mechanisms to
875 indicate the requester's level of willingness to permit this kind of interaction (for example, the
876 `IsPassive` attribute in `<samlp:AuthnRequest>`).
- 877 4. Eventually the responder SHOULD return a SAML response to the user agent to be returned to the
878 SAML requester. The SAML response is returned in the same fashion as described for the SAML
879 request in step 2.
- 880 5. Upon receiving the SAML response, the SAML requester returns an arbitrary HTTP response to the
881 user agent.

882 3.5.5.1 HTTP and Caching Considerations

883 HTTP proxies and the user agent intermediary should not cache SAML protocol messages. To ensure
884 this, the following rules SHOULD be followed.

885 When returning SAML protocol messages using HTTP 1.1, HTTP responders SHOULD:

- 886 • Include a `Cache-Control` header field set to "no-cache, no-store".

- Include a `Pragma` header field set to "no-cache".

There are no other restrictions on the use of HTTP headers.

3.5.5.2 Security Considerations

The presence of the user agent intermediary means that the requester and responder cannot rely on the transport layer for end-end authentication, integrity or confidentiality protection and must authenticate the messages received instead. SAML provides for a signature on protocol messages for authentication and integrity for such cases. Form-encoded messages MAY be signed before the base64 encoding is applied.

If the message is signed, the `Destination` XML attribute in the root SAML element of the protocol message MUST contain the URL to which the sender has instructed the user agent to deliver the message. The recipient MUST then verify that the value matches the location at which the message has been received.

This binding SHOULD NOT be used if the content of the request or response should not be exposed to the user agent intermediary. Otherwise, confidentiality of both SAML requests and SAML responses is OPTIONAL and depends on the environment of use. If confidentiality is necessary, SSL 3.0 [SSL3] or TLS 1.0 [RFC2246] SHOULD be used to protect the message in transit between the user agent and the SAML requester and responder.

In general, this binding relies on message-level authentication and integrity protection via signing and does not support confidentiality of messages from the user agent intermediary.

Note also that there is no mechanism defined to protect the integrity of the relationship between the SAML protocol message and the "RelayState" value, if any. That is, an attacker can potentially recombine a pair of valid HTTP responses by switching the "RelayState" values associated with each SAML protocol message. The individual "RelayState" and SAML message values can be integrity protected, but not the combination. As a result, the producer and consumer of "RelayState" information MUST take care not to associate sensitive state information with the "RelayState" value without taking additional precautions (such as based on the information in the SAML message).

[E90] When using RelayState in conjunction with HTTP redirects or response information, implementations MUST carefully sanitize the URL schemes they permit (for example, disallowing anything but "http" or "https"), and should disallow unencoded characters that may be used in mounting such attacks.

3.5.6 Error Reporting

A SAML responder that refuses to perform a message exchange with the SAML requester SHOULD return a response message with a second-level `<samlp:StatusCode>` value of `urn:oasis:names:tc:SAML:2.0:status:RequestDenied`.

HTTP interactions during the message exchange MUST NOT use HTTP error status codes to indicate failures in SAML processing, since the user agent is not a full party to the SAML protocol exchange.

For more information about SAML status codes, see the SAML assertions and protocols specification [SAMLCore].

3.5.7 Metadata Considerations

Support for the HTTP POST binding SHOULD be reflected by indicating URL endpoints at which requests and responses for a particular protocol or profile should be sent. Either a single endpoint or distinct request and response endpoints MAY be supplied.

1036 3.6 HTTP Artifact Binding

1037 In the HTTP Artifact binding, the SAML request, the SAML response, or both are transmitted by reference
1038 using a small stand-in called an artifact. A separate, synchronous binding, such as the SAML SOAP

binding, is used to exchange the artifact for the actual protocol message using the artifact resolution protocol defined in the SAML assertions and protocols specification [SAMLCore].

This binding MAY be composed with the HTTP Redirect binding (see Section 3.4) and the HTTP POST binding (see Section 3.5) to transmit request and response messages in a single protocol exchange using two different bindings.

3.6.1 Required Information

Identification: urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Artifact

Contact information: security-services-comment@lists.oasis-open.org

Description: Given below.

Updates: Effectively replaces the binding aspects of the Browser/Artifact profile in SAML V1.1 [SAML11Bind].

3.6.2 Overview

The HTTP Artifact binding is intended for cases in which the SAML requester and responder need to communicate using an HTTP user agent as an intermediary, but the intermediary's limitations preclude or discourage the transmission of an entire message (or message exchange) through it. This may be for technical reasons or because of a reluctance to expose the message content to the intermediary (and if the use of encryption is not practical).

Note that because of the need to subsequently resolve the artifact using another synchronous binding, such as SOAP, a direct communication path must exist between the SAML message sender and recipient in the reverse direction of the artifact's transmission (the receiver of the message and artifact must be able to send a <samlp:ArtifactResolve> request back to the artifact issuer). The artifact issuer must also maintain state while the artifact is pending, which has implications for load-balanced environments.

3.6.3 Message Encoding

There are two methods of encoding an artifact for use with this binding. One is to encode the artifact into a URL parameter and the other is to place the artifact in an HTML form control. When URL encoding is used, the HTTP GET method is used to deliver the message, while POST is used with form encoding. All endpoints that support this binding MUST support both techniques.

3.6.3.1 RelayState

RelayState data MAY be included with a SAML artifact transmitted with this binding. The value MUST NOT exceed 80 bytes in length and SHOULD be integrity protected by the entity creating the message independent of any other protections that may or may not exist during message transmission. Signing is not realistic given the space limitation, but because the value is exposed to third-party tampering, the entity SHOULD ensure that the value has not been tampered with by using a checksum, a pseudo-random value, or similar means.

If an artifact that represents a SAML request is accompanied by RelayState data, then the SAML responder MUST return its SAML protocol response using a binding that also supports a RelayState mechanism, and it MUST place the exact data it received with the artifact into the corresponding RelayState parameter in the response.

If no such value is included with an artifact representing a SAML request, or if the SAML response message is being generated without a corresponding request, then the SAML responder MAY include RelayState data to be interpreted by the recipient based on the use of a profile or prior agreement between the parties.

3.6.3.2 URL Encoding

To encode an artifact into a URL, the artifact value is URL-encoded and placed in a query string parameter named `SAMLart`.

If a “RelayState” value is to accompany the SAML artifact, it MUST be URL-encoded and placed in an additional query string parameter named `RelayState`.

3.6.3.3 Form Encoding

A SAML artifact is form-encoded by placing it in a hidden form control within a form as defined by [HTML401], chapter 17. The HTML document MUST adhere to the XHTML specification, [XHTML]. The form control MUST be named `SAMLart`. Any additional form controls or presentation MAY be included but MUST NOT be required in order for the recipient to process the artifact.

If a “RelayState” value is to accompany the SAML artifact, it MUST be placed in an additional hidden form control named `RelayState`, within the same form with the SAML message.

The `action` attribute of the form MUST be the recipient's HTTP endpoint for the protocol or profile using this binding to which the artifact is to be delivered. The `method` attribute MUST be set to "POST".

Any technique supported by the user agent MAY be used to cause the submission of the form, and any form content necessary to support this MAY be included, such as submit controls and client-side scripting commands. However, the recipient MUST be able to process the artifact without regard for the mechanism by which the form submission is initiated.

Note that any form control values included MUST be transformed so as to be safe to include in the XHTML document. This includes transforming characters such as quotes into HTML entities, etc.

3.6.4 Artifact Format

With respect to this binding, an artifact is a short, opaque string. Different types can be defined and used without affecting the binding. The important characteristics are the ability of an artifact receiver to identify the issuer of the artifact, resistance to tampering and forgery, uniqueness, and compactness.

The general format of any artifact includes a mandatory two-byte artifact type code and a two-byte index value identifying a specific endpoint of the artifact resolution service of the issuer, as follows:

<code>SAML_artifact</code>	<code>:= B64(</code> <code>TypeCode</code> <code> </code> <code>EndpointIndex</code> <code> </code> <code>RemainingArtifact)</code>
<code>TypeCode</code>	<code>:= Byte1Byte2</code>
<code>EndpointIndex</code>	<code>:= Byte1Byte2</code>

The notation `B64(``TypeCode``EndpointIndex``RemainingArtifact)` stands for the application of the base64 [RFC2045] transformation to the catenation of the `TypeCode`, `EndpointIndex`, and `RemainingArtifact`.

The following practices are RECOMMENDED for the creation of SAML artifacts:

- Each issuer is assigned an identifying URI, also known as the issuer's entity (or provider) ID. See Section 8.3.6 of [SAMLCore] for a discussion of this kind of identifier.
- The issuer constructs the `SourceID` component of the artifact by taking the SHA-1 hash of the identification URL. The hash value is NOT encoded into hexadecimal.
- The `MessageHandle` value is constructed from a cryptographically strong random or pseudorandom number sequence [RFC1750] generated by the issuer. The sequence consists of values of at least 16 bytes in size. These values should be padded as needed to a total length of 20 bytes.

The following describes the single artifact type defined by SAML V2.0. [E4]Although the general artifact

1123 structure resembles that used in prior versions of SAML and the type code of the single format described
1124 below does not conflict with previously defined formats, there is explicitly no correspondence between
1125 SAML V2.0 artifacts and those found in any previous specifications, and artifact formats not defined
1126 specifically for use with SAML V2.0 MUST NOT be used with this binding.

1127 3.6.4.1 Required Information

1128 **Identification:** urn:oasis:names:tc:SAML:2.0:artifact-04

1129 **Contact information:** security-services-comment@lists.oasis-open.org

1130 **Description:** Given below.

1131 **Updates:** None.

1132 3.6.4.2 Format Details

1133 SAML V2.0 defines an artifact type of type code 0x0004. This artifact type is defined as follows:

1134	TypeCode	:= 0x0004
1135	RemainingArtifact	:= SourceID MessageHandle
1136	SourceID	:= 20-byte_sequence
1137	MessageHandle	:= 20-byte_sequence

1138 SourceID is a 20-byte sequence used by the artifact receiver to determine artifact issuer identity and the
1139 set of possible resolution endpoints.

1140 It is assumed that the destination site will maintain a table of SourceID values as well as one or more
1141 indexed URL endpoints (or addresses) for the corresponding SAML responder. The SAML metadata
1142 specification [SAMLMeta] MAY be used for this purpose. On receiving the SAML artifact, the receiver
1143 determines if the SourceID belongs to a known artifact issuer and obtains the location of the SAML
1144 responder using the EndpointIndex before sending a SAML <samlp:ArtifactResolve> message
1145 to it.

1146 Any two artifact issuers with a common receiver MUST use distinct SourceID values. Construction of
1147 MessageHandle values is governed by the principle that they SHOULD have no predictable relationship
1148 to the contents of the referenced message at the issuing site and it MUST be infeasible to construct or
1149 guess the value of a valid, outstanding message handle.

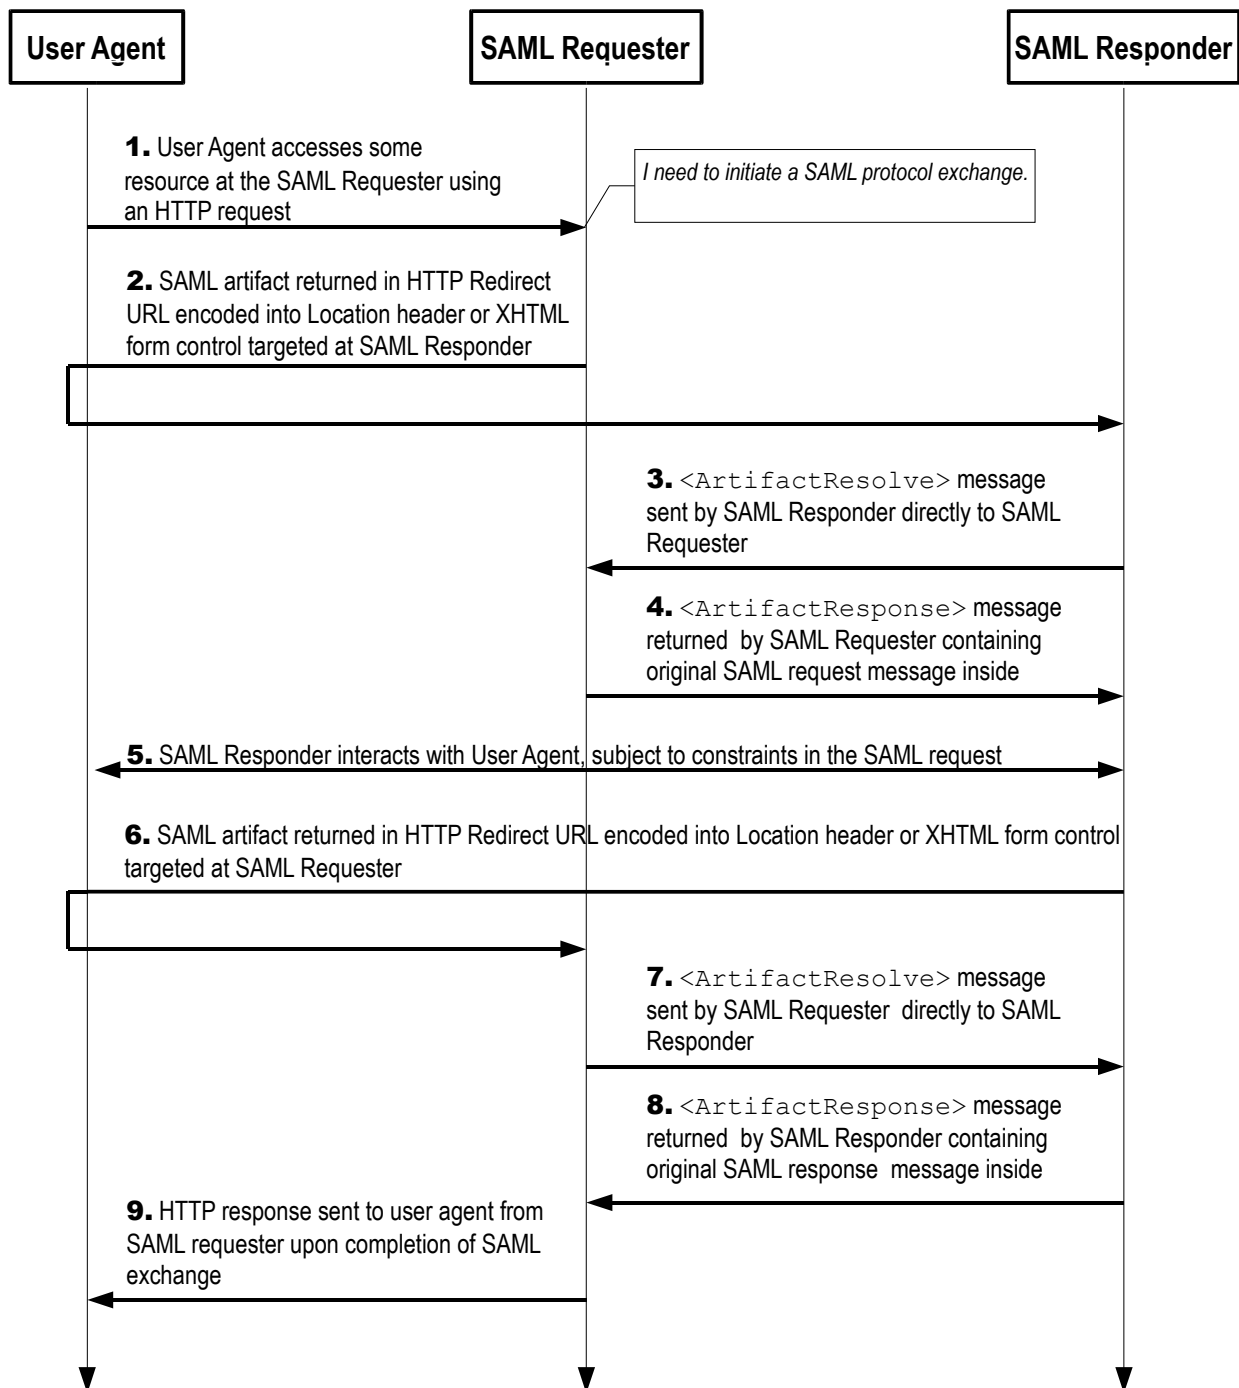

1150 3.6.5 Message Exchange

1151 The system model used for SAML conversations by means of this binding is a request-response model in
1152 which an artifact reference takes the place of the actual message content, and the artifact reference is
1153 sent to the user agent in an HTTP response and delivered to the message recipient in an HTTP request.
1154 The HTTP interactions before, between, and after these exchanges take place is unspecified. Both the
1155 SAML requester and responder are assumed to be HTTP responders.

1156 Additionally, it is assumed that on receipt of an artifact by way of the user agent, the recipient invokes a
1157 separate, direct exchange with the artifact issuer using the Artifact Resolution Protocol defined in
1158 [SAMLCore]. This exchange MUST use a binding that does not use the HTTP user agent as an
1159 intermediary, such as the SOAP binding. On the successful acquisition of a SAML protocol message, the
1160 artifact is discarded and the processing of the primary SAML protocol exchange resumes (or ends, if the
1161 message is a response).

1162 Issuing and delivering an artifact, along with the subsequent resolution step, constitutes half of the overall
1163 SAML protocol exchange. This binding can be used to deliver either or both halves of a SAML protocol
1164 exchange. A binding composable with it, such as the HTTP Redirect (see Section 3.4) or POST (see
1165 Section 3.5) binding, MAY be used to carry the other half of the exchange. The following sequence

1166 assumes that the artifact binding is used for both halves. See the diagram below illustrating the messages
1167 exchanged.

1168
1169

1. Initially, the user agent makes an arbitrary HTTP request to a system entity. In the course of processing the request, the system entity decides to initiate a SAML protocol exchange.

1170
1171

2. The system entity acting as a SAML requester responds to an HTTP request from the user agent by returning an artifact representing a SAML request.

1172
1173
1174
1175

- If URL-encoded, the artifact is returned encoded into the HTTP response's Location header, and the HTTP status MUST be either 303 or 302. The SAML requester MAY include additional presentation and content in the HTTP response to facilitate the user agent's transmission of the message, as defined in HTTP 1.1 [RFC2616]. The user

1176 agent delivers the artifact by issuing an HTTP GET request to the SAML responder.

1177 • If form-encoded, then the artifact is returned in an XHTML document containing the
1178 form and content defined in Section 3.6.3.3. The user agent delivers the artifact by
1179 issuing an HTTP POST request to the SAML responder.

1180 3. The SAML responder determines the SAML requester by examining the artifact (the exact process
1181 depends on the type of artifact), and issues a `<samlp:ArtifactResolve>` request containing
1182 the artifact to the SAML requester using a direct SAML binding, temporarily reversing roles.

1183 4. Assuming the necessary conditions are met, the SAML requester returns a
1184 `<samlp:ArtifactResponse>` containing the original SAML request message it wishes the
1185 SAML responder to process.

1186 5. In general, the SAML responder MAY respond to the SAML request by immediately returning a
1187 SAML artifact or MAY return arbitrary content to facilitate subsequent interaction with the user
1188 agent necessary to fulfill the request. Specific protocols and profiles may include mechanisms to
1189 indicate the requester's level of willingness to permit this kind of interaction (for example, the
1190 `IsPassive` attribute in `<samlp:AuthnRequest>`).

1191 6. Eventually the responder SHOULD return a SAML artifact to the user agent to be returned to the
1192 SAML requester. The SAML response artifact is returned in the same fashion as described for the
1193 SAML request artifact in step 2. The SAML requester determines the SAML responder by examining
1194 the artifact, and issues a `<samlp:ArtifactResolve>` request containing the artifact to the
1195 SAML responder using a [E31]synchronous SAML binding, as in step 3.

1196 7. Assuming the necessary conditions are met, the SAML responder returns a
1197 `<samlp:ArtifactResponse>` containing the SAML response message it wishes the requester
1198 to process, as in step 4.

1199 8. Upon receiving the SAML response, the SAML requester returns an arbitrary HTTP response to the
1200 user agent.

1201 3.6.5.1 HTTP and Caching Considerations

1202 HTTP proxies and the user agent intermediary should not cache SAML artifacts. To ensure this, the
1203 following rules SHOULD be followed.

1204 When returning SAML artifacts using HTTP 1.1, HTTP responders SHOULD:

- 1205 • Include a `Cache-Control` header field set to "no-cache, no-store".
- 1206 • Include a `Pragma` header field set to "no-cache".

1207 There are no other restrictions on the use of HTTP headers.

1208 3.6.5.2 Security Considerations

1209 This binding uses a combination of indirect transmission of a message reference followed by a direct
1210 exchange to return the actual message. As a result, the message reference (artifact) need not itself be
1211 authenticated or integrity protected, but the callback request/response exchange that returns the actual
1212 message MAY be mutually authenticated and integrity protected, depending on the environment of use.

1213 If the actual SAML protocol message is intended for a specific recipient, then the artifact's issuer MUST
1214 authenticate the sender of the subsequent `<samlp:ArtifactResolve>` message before returning the
1215 actual message.

1216 The transmission of an artifact to and from the user agent SHOULD be protected with confidentiality; SSL
1217 3.0 [SSL3] or TLS 1.0 [RFC2246] SHOULD be used. The callback request/response exchange that
1218 returns the actual message MAY be protected, depending on the environment of use.

1219 In general, this binding relies on the artifact as a hard-to-forge short-term reference and applies other
1220 security measures to the callback request/response that returns the actual message. All artifacts MUST
1221 have a single-use semantic enforced by the artifact issuer.

1222 Furthermore, it is RECOMMENDED that artifact receivers also enforce a single-use semantic on the
1223 artifact values they receive, to prevent an attacker from interfering with the resolution of an artifact by a
1224 user agent and then resubmitting it to the artifact receiver. If an attempt to resolve an artifact does not
1225 complete successfully, the artifact SHOULD be placed into a blocked artifact list for a period of time that
1226 exceeds a reasonable acceptance period during which the artifact issuer would resolve the artifact.

1227 Note also that there is no mechanism defined to protect the integrity of the relationship between the
1228 artifact and the "RelayState" value, if any. That is, an attacker can potentially recombine a pair of valid
1229 HTTP responses by switching the "RelayState" values associated with each artifact. As a result, the
1230 producer/consumer of "RelayState" information MUST take care not to associate sensitive state
1231 information with the "RelayState" value without taking additional precautions (such as based on the
1232 information in the SAML protocol message retrieved via artifact).

1233 [E90] When using RelayState in conjunction with HTTP redirects or response information,
1234 implementations MUST carefully sanitize the URL schemes they permit (for example, disallowing anything
1235 but "http" or "https"), and should disallow unencoded characters that may be used in mounting such
1236 attacks.

1237 [E59] Finally, note that the use of the `Destination` attribute in the root SAML element of the protocol
1238 message is unspecified by this binding, because of the message indirection involved.

1239 3.6.6 Error Reporting

1240 A SAML responder that refuses to perform a message exchange with the SAML requester SHOULD
1241 return a response message with a second-level `<samlp:StatusCode>` value of
1242 `urn:oasis:names:tc:SAML:2.0:status:RequestDenied`.

1243 HTTP interactions during the message exchange MUST NOT use HTTP error status codes to indicate
1244 failures in SAML processing, since the user agent is not a full party to the SAML protocol exchange.

1245 If the issuer of an artifact receives a `<samlp:ArtifactResolve>` message that it can understand, it
1246 MUST return a `<samlp:ArtifactResponse>` with a `<samlp:StatusCode>` value of
1247 `urn:oasis:names:tc:SAML:2.0:status:Success`, even if it does not return the corresponding
1248 message (for example because the artifact requester is not authorized to receive the message or the
1249 artifact is no longer valid).

1250 For more information about SAML status codes, see the SAML assertions and protocols specification
1251 [SAMLCore].

1252 3.6.7 Metadata Considerations

1253 Support for [E2]receiving messages using the HTTP Artifact binding SHOULD be reflected by indicating
1254 URL endpoints at which requests and responses for a particular protocol or profile should be sent. Either
1255 a single endpoint or distinct request and response endpoints MAY be supplied. Support for sending
1256 messages using this binding SHOULD be accompanied by one or more indexed
1257 `<md:ArtifactResolutionService>` endpoints for processing `<samlp:ArtifactResolve>`
1258 messages.

1259 3.6.8 Example SAML Message Exchange Using HTTP Artifact

1260 In this example, a `<LogoutRequest>` and `<LogoutResponse>` message pair is exchanged using the
1261 HTTP Artifact binding, with the artifact resolution taking place using the SOAP binding bound to HTTP.

1262 First, here are the actual SAML protocol messages being exchanged:

```

1263 <samlp:LogoutRequest xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
1264 xmlns="urn:oasis:names:tc:SAML:2.0:assertion"
1265 ID="d2b7c388cec36fa7c39c28fd298644a8" IssueInstant="2004-01-
1266 21T19:00:49Z" Version="2.0">
1267 <Issuer>https://IdentityProvider.com/SAML</Issuer>
1268 <NameID Format="urn:oasis:names:tc:SAML:2.0:nameid-
1269 format:persistent">005a06e0-ad82-110d-a556-004005b13a2b</NameID>
1270 <samlp:SessionIndex>1</samlp:SessionIndex>
1271 </samlp:LogoutRequest>

1272 <samlp:LogoutResponse xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
1273 xmlns="urn:oasis:names:tc:SAML:2.0:assertion"
1274 ID="b0730d21b628110d8b7e004005b13a2b"
1275 InResponseTo="d2b7c388cec36fa7c39c28fd298644a8"
1276 IssueInstant="2004-01-21T19:00:49Z" Version="2.0">
1277 <Issuer>https://ServiceProvider.com/SAML</Issuer>
1278 <samlp:Status>
1279 <samlp:StatusCode
1280 Value="urn:oasis:names:tc:SAML:2.0:status:Success"/>
1281 </samlp:Status>
1282 </samlp:LogoutResponse>

```

1283 The initial HTTP request from the user agent in step 1 is not defined by this binding. To initiate the logout
1284 protocol exchange, the SAML requester returns the following HTTP response, containing a SAML artifact.
1285 Note that the line feeds in the HTTP Location header below are a result of document formatting, and
1286 there are no line feeds in the actual header value.

```

1287 HTTP/1.1 302 Object Moved
1288 Date: 21 Jan 2004 07:00:49 GMT
1289 Location: https://ServiceProvider.com/SAML/SLO/Browser?
1290 SAMLart=AAQAADWNEw5VT47wcO4zX%2FiEzMmFQvGknDfws2ZtqSGdkNSbsW1cmVR0bzU
1291 %3D&RelayState=0043bfc1bc45110dae17004005b13a2b
1292 Content-Type: text/html; charset=iso-8859-1

```

1293 The SAML responder then resolves the artifact it received into the actual SAML request using the Artifact
1294 Resolution protocol and the SOAP binding in steps 3 and 4, as follows:

1295 Step 3:

```

1296 POST /SAML/Artifact/Resolve HTTP/1.1
1297 Host: IdentityProvider.com
1298 Content-Type: text/xml
1299 Content-Length: nnn
1300 SOAPAction: http://www.oasis-open.org/committees/security
1301 <SOAP-ENV:Envelope
1302   xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/">

```

1316 Step 4:

```

1317 HTTP/1.1 200 OK
1318 Date: 21 Jan 2004 07:00:49 GMT
1319 Content-Type: text/xml
1320 Content-Length: nnnn

```

```

1321 <SOAP-ENV:Envelope
1322   xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
1323   <SOAP-ENV:Body>
1324     <samlp:ArtifactResponse
1325       xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"
1326       xmlns="urn:oasis:names:tc:SAML:2.0:assertion"
1327       ID="_FQvGknDfws2Z" Version="2.0"
1328       InResponseTo="_6c3a4f8b9c2d"
1329       IssueInstant="2004-01-21T19:00:49Z">
1330       <Issuer>https://IdentityProvider.com/SAML</Issuer>
1331       <samlp:Status>
1332         <samlp:StatusCode
1333           Value="urn:oasis:names:tc:SAML:2.0:status:Success"/>
1334         </samlp:Status>
1335       <samlp:LogoutRequest ID="d2b7c388cec36fa7c39c28fd298644a8"
1336         IssueInstant="2004-01-21T19:00:49Z"
1337         Version="2.0">
1338         <Issuer>https://IdentityProvider.com/SAML</Issuer>
1339         <NameID Format="urn:oasis:names:tc:SAML:2.0:nameid-
1340 format:persistent">005a06e0-ad82-110d-a556-004005b13a2b</NameID>
1341         <samlp:SessionIndex>1</samlp:SessionIndex>
1342       </samlp:LogoutRequest>
1343     </samlp:ArtifactResponse>
1344   </SOAP-ENV:Body>
1345 </SOAP-ENV:Envelope>

```

1346 After any unspecified interactions may have taken place, the SAML responder returns a second SAML
 1347 artifact in its HTTP response in step 6:

```

1348 HTTP/1.1 302 Object Moved
1349 Date: 21 Jan 2004 07:05:49 GMT
1350 Location: https://IdentityProvider.com/SAML/SLO/Response?
1351 SAMLart=AAQAAFGIZXv5%2BQaBaE5qYurHWJOlnAgLAsqfnyidHIggbFU0mlSGFTyQiPc
1352 %3D&RelayState=0043bfc1bc45110dae17004005b13a2b
1353 Content-Type: text/html; charset=iso-8859-1

```

1354 The SAML responder then resolves the artifact it received into the actual SAML request using the Artifact
 1355 Resolution protocol and the SOAP binding in steps 7 and 8, as follows:

1356 Step 7:

```

1357 POST /SAML/Artifact/Resolve HTTP/1.1
1358 Host: ServiceProvider.com
1359 Content-Type: text/xml
1360 Content-Length: nnn
1361 SOAPAction: http://www.oasis-open.org/committees/security

1409 3.7 SAML URI Binding

1410 URIs are a protocol-independent means of referring to a resource. This binding is not a general SAML
 1411 request/response binding, but rather supports the encapsulation of a <samlp:AssertionIDRequest>
 1412 message with a single <saml:AssertionIDRef> into the resolution of a URI. The result of a successful
 1413 request is a SAML <saml:Assertion> element (but not a complete SAML response).

1414 Like SOAP, URI resolution can occur over multiple underlying transports. This binding has [E24]protocol-
 1415 independent aspects, but also calls out as mandatory the implementation of HTTP URIs.

1416 3.7.1 Required Information

1417 **Identification:** urn:oasis:names:tc:SAML:2.0:bindings:URI

1418 **Contact information:** security-services-comment@lists.oasis-open.org

1419 **Description:** Given below.

1420 **Updates:** None

1421 3.7.2 Protocol-Independent Aspects of the SAML URI Binding

1422 The following sections define aspects of the SAML URI binding that are independent of the underlying
 1423 transport protocol of the URI resolution process.

1424 3.7.2.1 Basic Operation

1425 A SAML URI reference identifies a specific SAML assertion. The result of resolving the URI MUST be a

message containing the assertion, or a transport-specific error. The specific format of the message depends on the underlying transport protocol. If the transport protocol permits the returned content to be described, such as HTTP 1.1 [RFC2616], then the assertion MAY be encoded in whatever format is permitted. If not, the assertion MUST be returned in a form which can be unambiguously interpreted as or transformed into an XML serialization of the assertion.

It MUST be the case that if the same URI reference is resolved in the future, then either the same SAML assertion, or an error, is returned. That is, the reference MAY be persistent but MUST consistently reference the same assertion, if any.

3.7.3 Security Considerations

Indirect use of a SAML assertion presents dangers if the binding of the reference to the result is not secure. The particular threats and their severity depend on the use to which the assertion is being put. In general, the result of resolving a URI reference to a SAML assertion SHOULD only be trusted if the requester can be certain of the identity of the responder and that the contents have not been modified in transit.

It is often not sufficient that the assertion itself be signed, because URI references are by their nature somewhat opaque to the requester. The requester SHOULD have independent means to ensure that the assertion returned is actually the one that is represented by the URI; this is accomplished by both authenticating the responder and relying on the integrity of the response.

3.7.4 MIME Encapsulation

For resolution protocols that support MIME as a content description and packaging mechanism, the resulting assertion SHOULD be returned as a MIME entity of type `application/samlassertion+xml`, as defined by [SAMLmime].

3.7.5 Use of HTTP URIs

A SAML authority that claims conformance to the SAML URI binding MUST implement support for HTTP. This section describes certain specifics of using HTTP URIs, including URI syntax, HTTP headers, and error reporting.

3.7.5.1 URI Syntax

In general, there are no restrictions on the permissible syntax of a SAML URI reference as long as the SAML authority responsible for the reference creates the message containing it. However, authorities MUST support a URL endpoint at which an HTTP request can be sent with a single query string parameter named `ID`. There MUST be no query string in the endpoint URL itself independent of this parameter.

For example, if the documented endpoint at an authority is "`https://saml.example.edu/assertions`", a request for an assertion with an `ID` of `abcde` can be sent to:

```
https://saml.example.edu/assertions?ID=abcde
```

Note that [E31]the URI syntax does not support the use of wildcards on such queries.

3.7.5.2 HTTP and Caching Considerations

HTTP proxies MUST NOT cache SAML assertions. To ensure this, the following rules SHOULD be followed.

When returning SAML assertions using HTTP 1.1, HTTP responders SHOULD:

- Include a `Cache-Control` header field set to "`no-cache, no-store`".

- Include a `Pragma` header field set to `"no-cache"`.

3.7.5.3 Security Considerations

RFC 2617 [RFC2617] describes possible attacks in the HTTP environment when basic or message-digest authentication schemes are used.

Use of SSL 3.0 [SSL3] or TLS 1.0 [RFC2246] is STRONGLY RECOMMENDED as a means of authentication, integrity protection, and confidentiality.

3.7.5.4 Error Reporting

As an HTTP protocol exchange, the appropriate HTTP status code SHOULD be used to indicate the result of a request. For example, a SAML responder that refuses to perform a message exchange with the SAML requester SHOULD return a `"403 Forbidden"` response. If the assertion specified is unknown to the responder, then a `"404 Not Found"` response SHOULD be returned. In these cases, the content of the HTTP body is not significant.

3.7.5.5 Metadata Considerations

Support for the URI binding over HTTP SHOULD be reflected by indicating a URL endpoint at which requests for arbitrary assertions are to be sent.

3.7.5.6 Example SAML Message Exchange Using an HTTP URI

Following is an example of a request for an assertion.

```
GET /SamlService?ID=abcde HTTP/1.1
Host: www.example.com
```

Following is an example of the corresponding response, which supplies the requested assertion.

```
HTTP/1.1 200 OK
Content-Type: application/samlassertion+xml
Cache-Control: no-cache, no-store
Pragma: no-cache
Content-Length: nnnn

<saml:Assertion ID="abcde" ...>
...
</saml:Assertion>
```

Appendix A. Registration of MIME media type application/samlassertion+xml

Introduction

This document defines a MIME media type -- `application/samlassertion+xml` -- for use with the XML serialization of SAML (Security Assertion Markup Language) assertions.

The SAML specification sets -- [SAMLv1.0], [SAMLv1.1], [SAMLv2.0] -- are work products of the OASIS Security Services Technical Committee [SSTC]. The SAML specifications define XML-based constructs with which one may make, and convey, security assertions. Using SAML, one can assert that an authentication event pertaining to some subject has occurred and convey said assertion to a relying party, for example.

SAML assertions, which are explicitly versioned, are defined by [SAMLv1Core], [SAMLv11Core], and [SAMLv2Core].

MIME media type name

`application`

MIME subtype name

`samlassertion+xml`

Required parameters

None

Optional parameters

`charset`

Same as `charset` parameter of `application/xml` [RFC3023].

Encoding considerations

Same as for `application/xml` [RFC3023].

Security considerations

Per their specification, `samlassertion+xml`-typed objects do not contain executable content. However, SAML assertions are XML-based objects [XML]. As such, they have all of the general security considerations presented in Section 10 of [RFC3023], as well as additional ones, since they are explicit security objects. For example, `samlassertion+xml`-typed objects will often contain data that may identify or pertain to a natural person, and may be used as a basis for sessions and access control decisions.

To counter potential issues, `samlassertion+xml`-typed objects contain data that should be signed appropriately by the sender. Any such signature must be verified by the recipient of the data - both as a valid signature, and as being the signature of the sender. Issuers of `samlassertion+xml`-typed objects containing SAMLv2 assertions may also encrypt all, or portions of, the assertions (see [SAMLv2Core]).

1593 In addition, SAML profiles and protocol bindings specify use of secure channels as appropriate.

1594 [SAMLv2.0] incorporates various privacy-protection techniques in its design. For example:
1595 opaque handles, specific to interactions between specific system entities, may be assigned to
1596 subjects. The handles are mappable to wider-context identifiers (e.g. email addresses, account
1597 identifiers, etc) by only the specific parties.

1598 For a more detailed discussion of SAML security considerations and specific security-related
1599 design techniques, please refer to the SAML specifications listed in the below bibliography. The
1600 specifications containing security-specific information have been explicitly listed for each version
1601 of SAML.

1602 Interoperability considerations

1603 SAML assertions are explicitly versioned. Relying parties should ensure that they observe
1604 assertion version information and behave accordingly. See chapters on SAML Versioning in
1605 [SAMLv1Core], [SAMLv11Core], or [SAMLv2Core], as appropriate.

1606 Published specification

1607 [SAMLv2Bind] explicitly specifies use of the `application/samlassertion+xml` MIME media
1608 type. However, it is conceivable that non-SAMLv2 assertions (i.e., SAMLv1 and/or SAMLv1.1)
1609 might in practice be conveyed using SAMLv2 bindings.

1610 Applications which use this media type

1611 Potentially any application implementing SAML, as well as those applications implementing
1612 specifications based on SAML, e.g. those available from the Liberty Alliance [LAP].

1613 Additional information

1614 Magic number(s)

1615 In general, the same as for `application/xml` [RFC3023]. In particular, the XML root element of the
1616 returned object will have a namespace-qualified name with:

- 1617 – a local name of: `Assertion`
- 1618 – a namespace URI of: one of the version-specific SAML assertion XML
1619 namespace URIs, as defined by the appropriate version-specific SAML "core"
1620 specification (see bibliography).

1621 With SAMLv2.0 specifically, the root element of the returned object may be either
1622 `<saml:Assertion>` or `<saml:EncryptedAssertion>`, where "saml" represents any XML
1623 namespace prefix that maps to the SAMLv2.0 assertion namespace URI:

1624 `urn:oasis:names:tc:SAML:2.0:assertion`

1625 File extension(s)

1626 None

1627 Macintosh File Type Code(s)

1628 None

Person & email address to contact for further information

This registration is made on behalf of the OASIS Security Services Technical Committee (SSTC). Please refer to the SSTC website for current information on committee chairperson(s) and their contact addresses: <http://www.oasis-open.org/committees/security/>. Committee members should submit comments and potential errata to the security-services@lists.oasis-open.org list. Others should submit them by filling out the web form located at http://www.oasis-open.org/committees/comments/form.php?wg_abbrev=security.

Additionally, the SAML developer community email distribution list, saml-dev@lists.oasis-open.org, may be employed to discuss usage of the `application/samlassertion+xml` MIME media type. The "saml-dev" mailing list is publicly archived here: <http://lists.oasis-open.org/archives/saml-dev/>. To post to the "saml-dev" mailing list, one must subscribe to it. To subscribe, send a message with the single word "subscribe" in the message body, to: saml-dev-request@lists.oasis-open.org.

Intended usage

COMMON

Author/Change controller

The SAML specification sets are a work product of the OASIS Security Services Technical Committee (SSTC). OASIS and the SSTC have change control over the SAML specification sets.

Appendix B. Acknowledgments

The editors would like to acknowledge the contributions of the OASIS Security Services Technical Committee, whose voting members at the time of publication were:

- Conor Cahill, AOL
- John Hughes, Atos Origin
- Hal Lockhart, BEA Systems
- Mike Beach, Boeing
- Rebekah Metz, Booz Allen Hamilton
- Rick Randall, Booz Allen Hamilton
- Ronald Jacobson, Computer Associates
- Gavenraj Sodhi, Computer Associates
- Thomas Wisniewski, Entrust
- Carolina Canales-Valenzuela, Ericsson
- Dana Kaufman, Forum Systems
- Irving Reid, Hewlett-Packard
- Guy Denton, IBM
- Heather Hinton, IBM
- Maryann Hondo, IBM
- Michael McIntosh, IBM
- Anthony Nadalin, IBM
- Nick Ragouzis, Individual
- Scott Cantor, Internet2
- Bob Morgan, Internet2
- Peter Davis, Neustar
- Jeff Hodges, Neustar
- Frederick Hirsch, Nokia
- Senthil Sengodan, Nokia
- Abbie Barbir, Nortel Networks
- Scott Kiestler, Novell
- Cameron Morris, Novell
- Paul Madsen, NTT
- Steve Anderson, OpenNetwork
- Ari Kermaier, Oracle
- Vamsi Motukuru, Oracle
- Darren Platt, Ping Identity
- Prateek Mishra, Principal Identity
- Jim Lien, RSA Security
- John Linn, RSA Security
- Rob Philpott, RSA Security
- Dipak Chopra, SAP
- Jahan Moreh, Sigaba
- Bhavna Bhatnagar, Sun Microsystems

- 1755 • Eve Maler, Sun Microsystems
- 1756 • Ronald Monzillo, Sun Microsystems
- 1757 • Emily Xu, Sun Microsystems
- 1758 • Greg Whitehead, Trustgenix

1759 The editors also would like to acknowledge the following former SSTC members for their contributions to
1760 this or previous versions of the OASIS Security Assertions Markup Language Standard:

- 1761 • Stephen Farrell, Baltimore Technologies
- 1762 • David Orchard, BEA Systems
- 1763 • Krishna Sankar, Cisco Systems
- 1764 • Zahid Ahmed, CommerceOne
- 1765 • Tim Alsop, CyberSafe Limited
- 1766 • Carlisle Adams, Entrust
- 1767 • Tim Moses, Entrust
- 1768 • Nigel Edwards, Hewlett-Packard
- 1769 • Joe Pato, Hewlett-Packard
- 1770 • Bob Blakley, IBM
- 1771 • Marlena Erdos, IBM
- 1772 • Marc Chanliau, Netegrity
- 1773 • Chris McLaren, Netegrity
- 1774 • Lynne Rosenthal, NIST
- 1775 • Mark Skall, NIST
- 1776 • Charles Knouse, Oblix
- 1777 • Simon Godik, Overxeer
- 1778 • Charles Norwood, SAIC
- 1779 • Evan Prodromou, Securant
- 1780 • Robert Griffin, RSA Security (former editor)
- 1781 • Sai Allarvarpu, Sun Microsystems
- 1782 • Gary Ellison, Sun Microsystems
- 1783 • Chris Ferris, Sun Microsystems
- 1784 • Mike Myers, Traceroute Security
- 1785 • Phillip Hallam-Baker, VeriSign (former editor)
- 1786 • James Vanderbeek, Vodafone
- 1787 • Mark O'Neill, Vordel
- 1788 • Tony Palmer, Vordel

1789 Finally, the editors wish to acknowledge the following people for their contributions of material used as
1790 input to the OASIS Security Assertions Markup Language specifications:

- 1791 • Thomas Gross, IBM
- 1792 • Birgit Pfitzmann, IBM

1793 The editors also would like to gratefully acknowledge Jahan Moreh of Sigaba, who during his tenure on
1794 the SSTC was the primary editor of the errata working document and who made major substantive
1795 contributions to all of the errata materials.

Appendix C. Notices

OASIS takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OASIS's procedures with respect to rights in OASIS specifications can be found at the OASIS website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementors or users of this specification, can be obtained from the OASIS Executive Director.

OASIS invites any interested party to bring to its attention any copyrights, patents or patent applications, or other proprietary rights which may cover technology that may be required to implement this specification. Please address the information to the OASIS Executive Director.

Copyright © OASIS Open 2005. All Rights Reserved.

This document and translations of it may be copied and furnished to others, and derivative works that comment on or otherwise explain it or assist in its implementation may be prepared, copied, published and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and this paragraph are included on all such copies and derivative works. However, this document itself may not be modified in any way, such as by removing the copyright notice or references to OASIS, except as needed for the purpose of developing OASIS specifications, in which case the procedures for copyrights defined in the OASIS Intellectual Property Rights document must be followed, or as required to translate it into languages other than English.

The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors or assigns.

This document and the information contained herein is provided on an "AS IS" basis and OASIS DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY RIGHTS OR ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.
